Amp is an open-source package designed to easily bring machine-learning to atomistic calculations. This project is being developed at Brown University in the School of Engineering, primarily by **Andrew Peterson** and **Alireza Khorshidi**, and is released under the GNU General Public License.

The latest stable release of Amp is version 1.0.1, released on January 25, 2023; see the [Release notes](#) page for a download link. Please see the project's [git repository](#) for the latest development version or a place to report an issue.

You can read about Amp in the below paper; if you find this project useful, we would appreciate if you cite this work:

Khorshidi & Peterson, “Amp: A modular approach to machine learning in atomistic simulations”, *Computer Physics Communications* 207:310-324, 2016.

An amp-users mailing list exists for general discussions about the use and development of Amp. You can subscribe via listserv at:

<https://listserv.brown.edu/?SUBED1=AMP-USERS&A=1>

Amp is now part of the Debian archives! This means it will soon be available via your package manager in linux releases like Ubuntu.

Amp is now installable via pip! This means you should be able to install with just:

```
$ pip3 install amp-atomistics
```

Manual:

CHAPTER 1

Introduction

Amp is an open-source package designed to easily bring machine-learning to atomistic calculations. This allows one to predict (or really, interpolate) calculations on the potential energy surface, by first building up a regression representation from a “training set” of atomic images. The Amp calculator works by first learning from any other calculator (usually quantum mechanical calculations) that can provide energy and forces as a function of atomic coordinates. Depending upon the model choice, the predictions from Amp can take place with arbitrary accuracy, approaching that of the original calculator.

Amp is designed to integrate closely with the [Atomic Simulation Environment](#) (ASE). As such, the interface is in pure python, although several compute-heavy parts of the underlying codes also have fortran versions to accelerate the calculations. The close integration with ASE means that any calculator that works with ASE - including EMT, GPAW, DACAPO, VASP, NWChem, and Gaussian - can easily be used as the parent method.

CHAPTER 2

Installation

Amp is python-based and is designed to integrate closely with the [Atomic Simulation Environment](#) (ASE). Because of this tight integration, *Amp* is compatible with every major electronic structure calculator and has ready access to all standard atomistic methods, such as structure optimization or molecular dynamics. In its most basic form, it has few requirements:

- Python, version 3.6 is recommended (but Python 2 is still supported)
- ASE
- NumPy + SciPy

To get more features, such as parallelization in training, a few more packages are recommended:

- Pexpect (or pxxssh)
- ZMQ (or PyZMQ, the python version of ØMQ).

Certain advanced modules may contain dependencies that will be noted when they are used; for example Tensorflow for the tflow module or matplotlib (version > 1.5.0) for the plotting modules.

We have three suggested means of installation, depending on your needs:

- via *Pip* (python's automatic package installer)
- via *Ubuntu's package manager*,
- or *manual installation*.

After you install, you should *run the tests*.

2.1 Pip

You can install quickly with using pip; if you have pip installed, you should be able to install the latest release quickly with:

```
$ pip3 install numpy
$ pip3 install amp-atomistics
```

If you already have numpy you should be able to skip the first line. If you would rather have the development version, replace the second line with:

```
$ pip3 install git+https://bitbucket.org/andrewpeterson/amp
```

Note that you may want to also supply the `-user` flag to pip3, which will install only in your home directory and not system wide. Another good strategy is to install inside of a virtualenv. You will need to take one of these approaches if installing on your own account within a cluster, for example.

If you see errors relating to fortran, make sure you have an f77 compiler installed (such as gfortran). If you see an error related to Python.h, make sure you have a version of python meant for compiling (e.g., *python3-dev* on ubuntu).

2.2 Ubuntu's package manager

If you use Debian or Ubuntu, *Amp* is now included in the package manager, and you can install just like any other program (e.g., through ‘Ubuntu Software’ or ‘synaptic’ package manager). Or most simply, just type:

```
$ sudo apt install python3-amp
```

Note that there is a long lead time between when we submit a package to Debian/Ubuntu and when it is included in an official release, so this version will typically be a bit old.

2.3 Manual installation

If the above fails, or you want to have your own version of the code that you can hack away on, you should try the manual installation, by following the below procedure.

Python version. We recommend Python 3.6. However, if you are Python 2 user the code will also work in Python 2 indefinitely. (But you should really change over to 3!)

Install ASE. We always test against the latest release of ASE, but slightly older versions (≥ 3.9) are likely to work as well. Follow the instructions at the [ASE](#) website. ASE itself depends upon python with the standard numeric and scientific packages. Verify that you have working versions of [NumPy](#) and [SciPy](#). We also recommend [matplotlib](#) (version $> 1.5.0$) in order to generate plots. After you are successful, you should be able to run the following without errors:

```
$ python3
>>> import ase
>>> import numpy
>>> import scipy
>>> import matplotlib
```

Get the code. You can download a stable (numbered) release, which is citable by DOI, via the links on the Release Notes page. You should make sure that the documentation that you are reading corresponds to the release you have downloaded; the documentation is included in the package or you can choose a version number on <http://amp.readthedocs.io>.

We are constantly improving *Amp* and adding features, so depending on your needs it may be preferable to use the development version rather than “stable” releases. We run daily unit tests to try to make sure that our development code works as intended. We recommend checking out or downloading the latest version of the code via [the project's bitbucket page](#). If you use git, check out the code with:

```
$ cd ~/path/to/my/codes
$ git clone https://andrewpeterson@bitbucket.org/andrewpeterson/amp.git
```

where you should replace ‘~/path/to/my/codes’ with wherever you would like the code to be located on your computer.

Simple option: use setup.py. After you have downloaded the code, the fastest way to compile it is by running (from inside the amp directory):

```
$ python setup.py install --user
```

If that works, you are done! If it doesn’t work or you want to use the fully manual option, keep reading.

Set the environment. You need to let your python version know where to find *Amp*. Add the following line to your ‘.bashrc’ (or other appropriate spot), with the appropriate path substituted for ‘~/path/to/my/codes’:

```
$ export PYTHONPATH=~/path/to/my/codes/amp:$PYTHONPATH
```

You can check that this works by starting python and typing the below command, verifying that the location listed from the second command is where you expect:

```
>>> import amp
>>> print(amp.__file__)
```

See also the section on parallel processing (in *Using Amp*) for any issues that arise in making the environment work with *Amp* in parallel.

Recommended: Build fortran modules. *Amp* works in pure python, however, it will be annoyingly slow unless the associated Fortran modules are compiled to speed up several parts of the code. The compilation of the Fortran code and integration with the python parts is accomplished with f2py, which is part of NumPy. A Fortran compiler will also be necessary on the system; a reasonable open-source option is GNU Fortran, or gfortran. This compiler will generate Fortran modules (.mod). gfortran will also be used by f2py to generate extension module fmodules.so on Linux or fmodules.pyd on Windows. We have included a *Makefile* that automatizes the building of Fortran modules. To use it, install [GNU Makefile](#) on your Linux distribution or macOS. Then you can simply do:

```
$ cd <installation-directory>/amp/
$ make
```

Note that you have to make sure your *f2py* is pointing to the right Python version.

If you do not have the GNU Makefile installed, you can prepare the Fortran extension modules manually in the following steps:

1. Compile model Fortran subroutines inside the model and descriptor folders by:

```
$ cd <installation-directory>/amp/model
$ gfortran -c neuralnetwork.f90
$ cd ../descriptor
$ gfortran -c cutoffs.f90
```

2. Move the modules “neuralnetwork.mod” and “cutoffs.mod” created in the last step, to the parent directory by:

```
$ cd ..
$ mv model/neuralnetwork.mod .
$ mv descriptor/cutoffs.mod .
```

3. Compile the model Fortran subroutines in companion with the descriptor and neuralnetwork subroutines by something like:

```
$ f2py -c -m fmodules model.f90 descriptor/cutoffs.f90 descriptor/gaussian.f90_
↳descriptor/zernike.f90 model/neuralnetwork.f90
```

Note that for Python3, you need to use *f2py3* instead of *f2py*.

or on a Windows machine by:

```
$ f2py -c -m fmodules model.f90 descriptor/cutoffs.f90 descriptor/gaussian.f90_
↳descriptor/zernike.f90 model/neuralnetwork.f90 --fcompiler=gnu95 --compiler=mingw32
```

Note that if you update your code (e.g., with ‘git pull origin master’) and the fortran code changes but your version of *fmodules.f90* is not updated, an exception will be raised telling you to re-compile your fortran modules.

2.4 Run the tests

We include tests in the package to ensure that it still runs as intended as we continue our development; we run these tests automatically with every commit (on bitbucket) to try to keep bugs out. It is a good idea to run these tests after you install the package to see if your installation is working. The tests are in the folder *tests*; they are designed to run with *nose*. If you have *nose* and GNU Makefile installed, simply do:

```
$ make py2tests      # (for Python2)
$ make py3tests      # (for Python3)
```

This will create a temporary directory and run the tests there. Otherwise, if you have only *nose* installed (and not GNU Makefile), run the commands below:

```
$ mkdir <installation-directory>/tests/amptests
$ cd <installation-directory>/tests/amptests
$ nosetests -v ../../
```

If you are familiar with ASE, the use of Amp should be intuitive. At its most basic, Amp behaves like any other ASE calculator, except that it has a key extra method, called `train()`, which allows you to fit the calculator to a set of atomic images. This means you can use Amp as a substitute for an expensive calculator in any atomistic routine, such as molecular dynamics, global optimization, transition-state searches, normal-mode analyses, phonon analyses, etc.

3.1 Basic use

To use Amp, you need to specify a *descriptor* and a *model*. The below shows a basic example of training Amp with Gaussian descriptors and a NeuralNetwork model—the Behler-Parinello scheme.

```
from amp import Amp
from amp.descriptor.gaussian import Gaussian
from amp.model.neuralnetwork import NeuralNetwork

calc = Amp(descriptor=Gaussian(), model=NeuralNetwork(),
            label='calc')
calc.train(images='my-images.traj')
```

After training is successful you can use your trained calculator just like any other ASE calculator (although you should be careful that you can only trust it within the trained regime). This will also result in the saving the calculator parameters to “<label>.amp”, which can be used to re-load the calculator in a future session:

```
calc = Amp.load('calc.amp')
```

The modular nature of Amp is meant such that you can easily mix-and-match different descriptor and model schemes. See the theory section for more details.

3.2 Adjusting convergence parameters

To control how tightly the energy and/or forces are converged, you can adjust the `LossFunction`. Just insert before the `calc.train` line some code like:

```
calc.model.lossfunction.parameters['convergence'].update(  
    {'energy_rmse': None,  
     'force_maxresid': 0.04})
```

You can see the adjustable parameters and their default values in the dictionary `default_parameters`:

```
>>> from amp.model import LossFunction  
>>> LossFunction.default_parameters  
{'convergence': {'energy_rmse': 0.001, 'force_rmse': None, 'energy_maxresid': None,  
↪ 'force_maxresid': None}}
```

Note that you can also set a maximum residual of any energy or force prediction with the appropriate keywords above.

To change how the code manages the regression process, you can use the `Regressor` class. For example, to switch from the `scipy`'s `fmin_bfgs` optimizer (the default) to `scipy`'s basin hopping optimizer, try inserting the following lines before initializing training:

```
from amp.regression import Regressor  
from scipy.optimize import basinhopping  
  
regressor = Regressor(optimizer=basinhopping, lossprime=False)  
calc.model.regressor = regressor
```

Note that not all optimizers take as argument the gradient of the objective function being optimized and *lossprime* has to be set to *False* accordingly as shown above.

3.3 Turning on/off force training

Most electronic structure codes also give forces (in addition to potential energy) for each image, and you can get a much more predictive fit if you include this information while training. However, this can create issues: training will tend to be slower than training energies only, convergence will be more difficult, and if there are inconsistencies in the training data (say if the calculator reports OK-extrapolated energies rather than force-consistent ones, or if there are egg-box errors), you might not be able to train at all. For this reason, Amp defaults to energy-only training, but you can turn on force-training via the convergence dictionary as noted above. Note that there is a *force_coefficient* keyword also fed to the `LossFunction` class which can control the relative weighting of the energy and force RMSEs used in the path to convergence.

```
from amp.model import LossFunction  
  
convergence = {'energy_rmse': 0.02, 'force_rmse': 0.04}  
calc.model.lossfunction = LossFunction(convergence=convergence,  
                                       force_coefficient=0.04)
```

3.4 Parallel processing

Most tasks in Amp are “embarrassingly parallel” and thus you should see a performance boost by specifying more cores. Our standard parallel processing approach requires the modules `ZMQ` (to pass messages between processes)

and `pxssh` (to establish SSH connections across nodes, and is only needed if parallelizing on more than one node).

The code will try to automatically guess the parallel configuration from the environment variables that your batching system produces, using the function `amp.utilities.assign_cores()`. (We only use SLURM on our system, so we welcome patches to get this utility working on other systems!) If you want to override the automatic guess, use the `cores` keyword when initializing Amp. To specify serial operation, use `cores=1`; to specify (for example) 8 cores on only a single node, use `cores=8` or `cores={'localhost': 8}`. For parallel operation, `cores` should be a dictionary where the keys are the hostnames and the values are the number of processors (cores) available on that node; e.g.,

```
cores = {'node241': 16,
        'node242': 16}
```

(One of the keys in the dictionary could also be `localhost`, as in the single-node example. Using `localhost` just prevents it from establishing an extra SSH connection.)

For this to work on multiple nodes, you need to be able to freely SSH between nodes on your system. Typically, this means that once you are logged in to your cluster you have public/private keys in use to ssh between nodes. If you can run `ssh localhost` without it asking you for a password, this is likely to work for you.

This also assumes that your environment is identical each time you SSH into a node; that is, all the packages such as ASE, Amp, ZMQ, etc., are available in the same version. Generally, if you are setting your environment with a `.bashrc` or `.modules` file this will just work. However, if you need to set your environment variables on the machine that is being ssh'd to, you can do so with the `envcommand` keyword, which you might set to

```
envcommand = 'export PYTHONPATH=/path/to/amp:$PYTHONPATH'
```

This `envcommand` can be passed as a keyword to the initialization of the Amp class. Ultimately, Amp stores these and passes them around in a configuration dictionary called `parallel`, so if you are calling descriptor or model functions directly you may need to construct this dictionary, which has the form `parallel={'cores': ..., 'envcommand': ...}`.

3.5 Advanced use

Under the hood, the train function is pretty simple; it just runs:

```
images = hash_images(images, ...)
self.descriptor.calculate_fingerprints(images, ...)
result = self.model.fit(images, self.descriptor, ...)
if result is True:
    self.save(filename)
```

- In the first line, the images are read and converted to a dictionary, addressed by a hash. This makes addressing the images simpler across modules and eliminates duplicate images. This also facilitates keeping a database of fingerprints, such that in future scripts you do not need to re-fingerprint images you have already encountered.
- In the second line, the descriptor converts the images into fingerprints, one fingerprint per image. There are two possible modes a descriptor can operate in: “image-centered” in which one vector is produced per image, and “atom-centered” in which one vector is produced per atom. That is, in atom-centered mode the image’s fingerprint will be a list of lists. The resulting fingerprint is stored in `self.descriptor.fingerprints`, and the mode is stored in `self.parameters.mode`.
- In the third line, the model (e.g., a neural network) is fit to the data. As it is passed a reference to `self.descriptor`, it has access to the fingerprints as well as the mode. Many options are available to customize this in terms of the loss function, the regression method, etc.
- In the final pair of lines, if the target fit was achieved, the model is saved to disk.

3.6 Re-training and resuming training

If training is successful, Amp saves the parameters into an '<label>.amp' file (by default the label is 'amp', so this file is 'amp.amp'). You can load the pretrained calculator and re-train it further with tighter convergence criteria or more/different images. You can specify if the pre-trained amp.amp will be overwritten by the re-trained one through the key word 'overwrite' (default is False).

```
calc = Amp.load('amp.amp')
calc.model.lossfunction = LossFunction(convergence=convergence)
calc.train(overwrite=True, images='training.traj')
```

If training does not succeed, Amp raises a `TrainingConvergenceError`. You can use this within your scripts to catch when training succeeds or fails, for example:

```
from amp.utilities import TrainingConvergenceError

...

try:
    calc.train(images)
except TrainingConvergenceError:
    # Whatever you want to happen if training fails;
    # e.g., refresh parameters and train again.
```

The neural network calculator saves checkpoints, and you can use these to resume a training run or to monitor the performance on a validation set. Use the `checkpoints` keyword to control this behavior. If your script times out before training finishes, you can generally just re-submit the same script; if the code finds a checkpoint file it will load the parameters from the checkpoint file and resume training from that point. This will be noted in the log file.

3.7 Global search in the parameter space

If the model is trained with minimizing a loss function which has a non-convex form, it might be desirable to perform a global search in the parameter space in prior to a gradient-descent optimization algorithm. That is, in the first step we do a random search in an area of parameter space including multiple basins (each basin has a local minimum). Next we take the parameters corresponding to the minimum loss function found, and start a gradient-descent optimization to find the local minimum of the basin found in the first step. Currently there exists a built-in global-search optimizer inside Amp which uses simulated-annealing algorithm. The module is based on the open-source simulated-annealing code of Wagner and Perry [1], but has been brought into the context of Amp. To use this module, the calculator object should be initiated as usual:

```
from amp import Amp
calc = Amp(descriptor=..., model=...)
images = ...
```

Then the calculator object and the images are passed to the `Annealer` module and the simulated-annealing search is performed by reducing the temperature from the initial maximum value T_{max} to the final minimum value T_{min} in number of steps `steps`:

```
from amp.utilities import Annealer
Annealer(calc=calc, images=images, Tmax=20, Tmin=1, steps=4000)
```

If T_{max} takes a small value (greater than zero), then the algorithm reduces to the simple random-walk search. Finally the usual `train()` method is called to continue from the best parameters found in the last step:

```
calc.train(images=images,)
```

4.1 Mailing list

An amp-users listserv is available for general discussion, troubleshooting, suggestions, etc. It is available at

<https://listserv.brown.edu/?A0=AMP-USERS>

The archives of this list are also available to members of the list. A direct link to subscribe to the list is at

<https://listserv.brown.edu/?SUBED1=AMP-USERS&A=1>

4.2 Bugs and issues

To report bugs, issues, works-in-progress, or feature requests (although those might best be first discussed on amp-users), please use our Issue Tracker on the repository page. It is available at

<https://bitbucket.org/andrewpeterson/amp/issues>

4.3 Contributions

You are welcome to contribute to this project. See the *Development* page.

According to the Born-Oppenheimer approximation, the ground-state potential energy of an atomic configuration is dictated solely by the nuclear coordinates (under certain conditions, such as the absence of external fields and constant charge). The potential energy is in general a very complicated function of the nuclear coordinates; it in theory can be calculated by directly solving the Schrodinger equation. However, in practice, an exact analytical solution to the many-body Schrodinger equation is very difficult (if not impossible), and most electronic structure codes provide a point-by-point approximation to the ground-state potential energy for given nuclear configurations.

Given enough example calculations from any electronic structure calculator, the idea is then to approximate the potential energy with a regression model:

$$\mathbf{R} \xrightarrow{\text{regression}} E = E(\mathbf{R}),$$

where \mathbf{R} is the position of atoms in the system.

5.1 Atomic representation of potential energy

In order to have a potential function which is simultaneously applicable to systems of different sizes, the total potential energy of the system can to be broken up into atomic energy contributions:

$$E(\mathbf{R}) = \sum_{\text{atom}=1}^N E_{\text{atom}}(\mathbf{R}).$$

The above expansion can be justified by assembling the atomic configuration by bringing atoms close to each other one by one. Then the atomic energy contributions (instead of the energy of the whole system at once) can be approximated using a regression method:

$$\mathbf{R} \xrightarrow{\text{regression}} E_{\text{atom}} = E_{\text{atom}}(\mathbf{R}).$$

5.2 Descriptor

A better interpolation can be achieved if an appropriate symmetry function \mathbf{G} of atomic coordinates, approximating the functional dependence of local energetics, is used as the input of the regression operator:

$$\mathbf{R} \xrightarrow{\mathbf{G}} \mathbf{G}(\mathbf{R}) \xrightarrow{\text{regression}} E_{\text{atom}} = E_{\text{atom}}(\mathbf{G}(\mathbf{R})).$$

In net, this results in a scheme like shown below. The symmetry functions create “feature vectors” which in turn are fed into a machine-learning regression model.

5.2.1 Gaussian

A Gaussian descriptor \mathbf{G} as a function of pair-atom distances and three-atom angles has been suggested by Behler [1], and is implemented within Amp. Radial fingerprints of the Gaussian type capture the interaction of atom i with all atoms j as the sum of Gaussians with width η and center (offset) R_s ,

$$G_i^{\text{II}} = \sum_{\substack{\text{atoms } j \text{ within } R_c \\ \text{distance of atom } i \\ j \neq i}} e^{-\eta(R_{ij}-R_s)^2/R_c^2} f_c(R_{ij}).$$

By specifying many values of η and R_s we can begin to build a feature vector for regression.

The next type is the angular fingerprint accounting for three-atom interactions. The Gaussian angular fingerprints are computed for all triplets of atoms i , j , and k by summing over the cosine values of the angles $\theta_{ijk} = \cos^{-1} \left(\frac{\mathbf{R}_{ij} \cdot \mathbf{R}_{ik}}{R_{ij} R_{ik}} \right)$, ($\mathbf{R}_{ij} = \mathbf{R}_i - \mathbf{R}_j$), centered at atom i , according to

$$G_i^{\text{IV}} = 2^{1-\zeta} \sum_{\substack{\text{atoms } j, k \text{ within } R_c \\ \text{distance of atom } i \\ j, k \neq i \\ (j \neq k)}} (1 + \lambda \cos \theta_{ijk})^\zeta e^{-\eta(R_{ij}^2 + R_{ik}^2 + R_{jk}^2)/R_c^2} f_c(R_{ij}) f_c(R_{ik}) f_c(R_{jk}),$$

with parameters λ , η , and ζ , which again can be chosen to build more elements of a feature vector.

There is an alternative angular symmetry function that ignores the separation between atoms j and k ; this can be better behaved than the previous function.

$$G_i^{\text{V}} = 2^{1-\zeta} \sum_{\substack{\text{atoms } j, k \text{ within } R_c \\ \text{distance of atom } i \\ j, k \neq i \\ (j \neq k)}} (1 + \lambda \cos \theta_{ijk})^\zeta e^{-\eta(R_{ij}^2 + R_{ik}^2)/R_c^2} f_c(R_{ij}) f_c(R_{ik}),$$

The cutoff function $f_c(R_{ij})$ in the above equations defines the energetically relevant local environment with value one at $R_{ij} = 0$ and zero at $R_{ij} = R_c$, where R_c is the cutoff radius. In order to have a continuous force-field, the cutoff function $f_c(R_{ij})$ as well as its first derivative should be continuous in $R_{ij} \in [0, \infty)$. One possible expression for such a function as proposed by Behler [1] is

$$f_c(r) = \begin{cases} 0.5 \left(1 + \cos \left(\pi \frac{r}{R_c} \right) \right) & \text{for } r \leq R_c, \\ 0 & \text{for } r > R_c. \end{cases}$$

Another more general choice for the cutoff function is the following polynomial [5]:

$$f_c(r) = \begin{cases} 1 + \gamma \cdot (r/R_c)^{\gamma+1} - (\gamma+1)(r/R_c)^\gamma & \text{if } r \leq R_c, \\ 0 & \text{if } r > R_c, \end{cases}$$

with a user-specified parameter γ that determines the rate of decay of the cutoff function as it extends from $r = 0$ to $r = R_c$.

The figure below shows how components of the fingerprints \mathbf{G}^{II} and \mathbf{G}^{IV} change with, respectively, distance R_{ij} between the pair of atoms i and j and the valence angle θ_{ijk} between the triplet of atoms i , j , and k with central atom i :

5.2.2 Zernike

A three-dimensional Zernike descriptor is also available inside Amp, and can be used as the atomic environment descriptor. The Zernike-type descriptor has been previously used in the machine-learning community extensively, but it has been suggested here for the first time for representing the local chemical environment. Zernike moments are basically a tensor product between spherical harmonics (complete and orthogonal on the surface of the unit sphere), and Zernike polynomials (complete and orthogonal within the unit sphere). Zernike descriptor components for each integer degree are then defined as the norm of Zernike moments with the same corresponding degree. For more details on the Zernike descriptor the reader is referred to the nice paper of Novotni and Klein [2].

Inspired by Bartok et. al. [3], to represent the local chemical environment of atom i , an atomic density function $\rho_i(\mathbf{r})$ is defined for each atomic local environment as the sum of delta distributions shifted to atomic positions:

$$\rho_i(\mathbf{r}) = \sum_{\substack{\text{atoms } j \text{ within } R_c \\ \text{distance of atom } i \\ j \neq i}} \eta_j \delta(\mathbf{r} - \mathbf{R}_{ij}) f_c(\|\mathbf{R}_{ij}\|),$$

Next, components of the Zernike descriptor are computed from Zernike moments of the above atomic density distribution for each atom i .

The figure below shows how components of the Zernike descriptor vary with pair-atom distance, three-atom angle, and four-atom dehidral angle. It is important to note that components of the Gaussian descriptor discussed above are non-sensitive to the four-atom dehidral angle of the following figure.

5.2.3 Bispectrum

Bispectrum of four-dimensional spherical harmonics have been suggested by Bartok et al. [3] to be invariant under rotation of the local atomic environment. In this approach, the atomic density distribution defined above is first mapped onto the surface of unit sphere in four dimensions. Consequently, Bartok et al. have shown that the bispectrum of this mapping can be used as atomic environment descriptor. We refer the reader to the original paper [3] for mathematical details. This approach of describing local environment is also available inside Amp.

5.3 Regression Model

The general purpose of the regression model $x \xrightarrow{\text{regression}} y$ with input x and output y is to approximate the function $y = f(x)$ by using sample training data points (x_i, y_i) . The intent is to later use the approximated f for input data x_j (other than x_i in the training data set), and make predictions for y_j . Typical regression models include Gaussian processes, support vector regression, and neural network.

5.3.1 Neural network model

A neural network model is basically a very simple model of how the nervous system processes information. The first mathematical model was developed in 1943 by McCulloch and Pitts [4] for classification purposes; biological neurons either send or do not send a signal to the neighboring neuron. The model was soon extended to do linear and nonlinear regression, by replacing the binary activation function with a continuous function. The basic functional unit of a neural network is called “node”. A number of parallel nodes constitute a layer. A feed-forward neural network consists of at least an input layer plus an output layer. When approximating the PES, the output layer has just one neuron representing the potential energy. For a more robust interpolation, a number of “hidden layers” may exist in the neural network as well; the word “hidden” refers to the fact that these layers have no physical meaning. A schematic of a typical feed-forward neural network is shown below. In each node a number of inputs is multiplied by the corresponding weights and summed up with a constant bias. An activation function then acts upon the summation and an output is generated. The output is finally sent to the neighboring neuron in the next layer. Typically used activation functions are hyperbolic tangent, sigmoid, Gaussian, and linear functions. The unbounded linear activation function is particularly useful in the last hidden layer to scale neural network outputs to the range of reference values. For our purpose, the output of neural network represents energy of atomic system.

6.1 People

This project is developed primarily by **Andrew Peterson** and **Alireza Khorshidi** in the Brown University School of Engineering. Specific credits:

- Andrew Peterson: lead, PI, many modules
- Alireza Khorshidi: many modules, Zernike descriptor
- Zack Ulissi: tensorflow version of neural network
- Muammar El Khatib: general contributions

We are also indebted to Nongnuch Artrith (MIT) and Pedro Felzenszwalb (Brown) for inspiration and technical discussion.

6.2 Citations

We would appreciate if you cite the below publication for any use of Amp or its methods:

7.1 1.0.1

Release date: January 25, 2023

- Fixed setup.py and pip installation to properly bring in new modules.

Permanently available at <https://doi.org/10.5281/zenodo.7568980>

7.2 1.0

Release date: August 31, 2022

- Added the Nearsighted Force Training approach.
- Added image and feature selection methods.
- Added offsets in G2 fingerprints; that is, G2 symmetry functions with shifted Gaussian centers can be used.
- Fast force calls are now supported, via third-party codes. See the fast force calls portion of the documentation.
- A *documented* bootstrap module, complete with examples of use, is included for uncertainty predictions.
- Improved interprocess communication which should reduce network traffic for parallel jobs.
- Amp is now part of the Debian archives! This means it should soon be available in package managers for linux releases such as Ubuntu.
- The convergence plots (via `amp.analysis` and `amp-plotconvergence`) now handle multiple training attempts from a single log file.
- The image hashing routine, used to uniquely identify images, has been updated to correctly handle permutations in very large atomic systems. (Note this means that images hashed with a prior version of Amp will have a different unique identifier, so you should not mix databases of fingerprints.)
- Added Kernel Ridge Regression to Amp.

- Incorporation of Behler’s G5 angular symmetry function.
- Neural network training scripts are now re-submittable; that is, if a job times out it can be re-submitted (unmodified) and will pick up from the last checkpoint.

Permanently available at <https://doi.org/10.5281/zenodo.7035955>

7.3 0.6.1

Release date: July 19, 2018

- Installation via pip is now possible.

7.4 0.6

Release date: July 31, 2017

- Python 3 compatibility. Following the release of python3-compatible ASE, we decided to jump on the wagon ourselves. The code should still work fine in python 2.7. (The exception is the tensorflow module, which still only lives inside python 2, unfortunately.)
- A community page has been added with resources such as the new mailing list and issue tracker.
- The default convergence parameters have been changed to energy-only training; force-training can be added by the user via the loss function. This makes convergence easier for new users.
- Convergence plots show maximum residuals as well as root mean-squared error.
- Parameters to make the Gaussian feature vectors are now output to the log file.
- The helper function `make_symmetry_functions()` has been added to more easily customize Gaussian fingerprint parameters.

Permanently available at <https://doi.org/10.5281/zenodo.836788>

7.5 0.5

Release date: February 24, 2017

The code has been significantly restructured since the previous version, in order to increase the modularity; much of the code structure has been changed since v0.4. Specific changes below:

- A parallelization scheme allowing for fast message passing with ZeroMQ.
- A simpler database format based on files, which optionally can be compressed to save disk space.
- Incorporation of an experimental neural network model based on google’s TensorFlow package. Requires TensorFlow version 0.11.0.
- Incorporation of an experimental bootstrap module for uncertainty analysis.

Permanently available at <https://doi.org/10.5281/zenodo.322427>

7.6 0.4

Release date: February 29, 2016

Corresponds to the publication of Khorshidi, A; Peterson*, AA. Amp: a modular approach to machine learning in atomistic simulations. Computer Physics Communications 207:310-324, 2016. <http://dx.doi.org/10.1016/j.cpc.2016.05.010>

Permanently available at <https://doi.org/10.5281/zenodo.46737>

7.7 0.3

Release date: July 13, 2015

First release under the new name “Amp” (Atomistic Machine-Learning Package/Potentials).

Permanently available at <https://doi.org/10.5281/zenodo.20636>

7.8 0.2

Release date: July 13, 2015

Last version under the name “Neural: Machine-learning for Atomistics”. Future versions are named “Amp”.

Available as the v0.2 tag in <https://bitbucket.org/andrewpeterson/neural/commits/tag/v0.2>

7.9 0.1

Release date: November 12, 2014

(Package name: Neural: Machine-Learning for Atomistics)

Permanently available at <https://doi.org/10.5281/zenodo.12665>.

7.10 Alpha version milestones

First public code (bitbucket): September 1, 2014.

First project commit: May 5, 2014.

8.1 A basic fitting script

The below script uses Gaussian descriptors with a neural network backend — the Behler-Parrinello approach — to train energies only to a training set made by the script. Note that most of the code is just generating the training data, and the training takes place in a couple of lines.

```
"""Simple test of the Amp calculator, using Gaussian descriptors and neural
network model. Randomly generates data with the EMT potential in MD
simulations."""

import os
from ase import Atoms, Atom, units
import ase.io
from ase.calculators.emt import EMT
from ase.build import fcc110
from ase.md.velocitydistribution import MaxwellBoltzmannDistribution
from ase.md import VelocityVerlet
from ase.constraints import FixAtoms

from amp import Amp
from amp.descriptor.gaussian import Gaussian
from amp.model.neuralnetwork import NeuralNetwork

def generate_data(count, filename='training.traj'):
    """Generates test or training data with a simple MD simulation."""
    if os.path.exists(filename):
        return
    traj = ase.io.Trajectory(filename, 'w')
    atoms = fcc110('Pt', (2, 2, 2), vacuum=7.)
    atoms.extend(Atoms([Atom('Cu', atoms[7].position + (0., 0., 2.5)),
                        Atom('Cu', atoms[7].position + (0., 0., 5.))]))
    atoms.set_constraint(FixAtoms(indices=[0, 2]))
```

(continues on next page)

(continued from previous page)

```

atoms.calc = EMT()
atoms.get_potential_energy()
traj.write(atoms)
MaxwellBoltzmannDistribution(atoms, 300. * units.kB)
dyn = VelocityVerlet(atoms, dt=1. * units.fs)
for step in range(count - 1):
    dyn.run(50)
    traj.write(atoms)

generate_data(20)

calc = Amp(descriptor=Gaussian(),
            model=NeuralNetwork(hiddenlayers=(10, 10, 10)))
calc.train(images='training.traj')

```

Note you can monitor the progress of the training by typing *amp-plotconvergence amp-log.txt*, which will create a file called *convergence.pdf*.

8.2 A basic script with forces

The below script trains both energy and forces to the same training set as above. Note this may take some time to run, which will depend upon the initial guess for the neural network parameters that is randomly generated. Try decreasing the *force_rmse* convergence parameter if you would like faster results.

```

"""Simple test of the Amp calculator, using Gaussian descriptors and neural
network model. Randomly generates data with the EMT potential in MD
simulations."""

import os
from ase import Atoms, Atom, units
import ase.io
from ase.calculators.emt import EMT
from ase.build import fcc110
from ase.md.velocitydistribution import MaxwellBoltzmannDistribution
from ase.md import VelocityVerlet
from ase.constraints import FixAtoms

from amp import Amp
from amp.descriptor.gaussian import Gaussian
from amp.model.neuralnetwork import NeuralNetwork
from amp.model import LossFunction

def generate_data(count, filename='training.traj'):
    """Generates test or training data with a simple MD simulation."""
    if os.path.exists(filename):
        return
    traj = ase.io.Trajectory(filename, 'w')
    atoms = fcc110('Pt', (2, 2, 2), vacuum=7.)
    atoms.extend(Atoms([Atom('Cu', atoms[7].position + (0., 0., 2.5)),
                        Atom('Cu', atoms[7].position + (0., 0., 5.))]))
    atoms.set_constraint(FixAtoms(indices=[0, 2]))
    atoms.calc = EMT()

```

(continues on next page)

(continued from previous page)

```

atoms.get_potential_energy()
traj.write(atoms)
MaxwellBoltzmannDistribution(atoms, 300. * units.kB)
dyn = VelocityVerlet(atoms, dt=1. * units.fs)
for step in range(count - 1):
    dyn.run(50)
    traj.write(atoms)

generate_data(20)

calc = Amp(descriptor=Gaussian(),
            model=NeuralNetwork(hiddenlayers=(10, 10, 10)))
calc.model.lossfunction = LossFunction(convergence={'energy_rmse': 0.02,
                                                    'force_rmse': 0.02})
calc.train(images='training.traj')

```

Note you can monitor the progress of the training by typing *amp-plotconvergence amp-log.txt*, which will create a file called *convergence.pdf*.

8.3 Examining fingerprints

With the modular nature, it's straightforward to analyze how fingerprints change with changes in images. The below script makes an animated GIF that shows how a fingerprint about the O atom in water changes as one of the O-H bonds is stretched. Note that most of the lines of code below are either making the atoms or making the figure; very little effort is needed to produce the fingerprints themselves—this is done in three lines.

```

# Make a series of images.
import numpy as np
from ase.structure import molecule
from ase import Atoms
atoms = molecule('H2O')
atoms.rotate('y', -np.pi/2.)
atoms.set_pbc(False)
displacements = np.linspace(0.9, 8.0, 20)
vec = atoms[2].position - atoms[0].position
images = []
for displacement in displacements:
    atoms = Atoms(atoms)
    atoms[2].position = (atoms[0].position + vec * displacement)
    images.append(atoms)

# Fingerprint using Amp.
from amp.descriptor.gaussian import Gaussian
descriptor = Gaussian()
from amp.utilities import hash_images
images = hash_images(images, ordered=True)
descriptor.calculate_fingerprints(images)

# Plot the data.
from matplotlib import pyplot

def barplot(hash, name, title):
    """Makes a barplot of the fingerprint about the O atom."""

```

(continues on next page)

(continued from previous page)

```
fp = descriptor.fingerprints[hash][0]
fig, ax = pyplot.subplots()
ax.bar(range(len(fp[1])), fp[1])
ax.set_title(title)
ax.set_ylim(0., 2.)
ax.set_xlabel('fingerprint')
ax.set_ylabel('value')
fig.savefig(name)

for index, hash in enumerate(images.keys()):
    barplot(hash, 'bplot-%02i.png' % index,
            '%.2f$\\times$ equilibrium O-H bondlength'
            % displacements[index])

# For fun, make an animated gif.
import os
filenames = ['bplot-%02i.png' % index for index in range(len(images))]
command = ('convert -delay 100 %s -loop 0 animation.gif' %
          ' '.join(filenames))
os.system(command)
```

9.1 Convergence plots

You can use the tool called *amp-plotconvergence* to help you examine the output of an Amp log file. Run *amp-plotconvergence -h* for help at the command line.

You can also access this tool as `plot_convergence()` from the `amp.analysis` module.

9.2 Other plots

There are several other plotting tools within the `amp.analysis` module, including `plot_parity_and_error()` for making parity and error plots, and `plot_sensitivity()` for examining the sensitivity of the model output to the model parameters. These modules should produce plots like below; in the order parity, error, and sensitivity from left to right. See the module autodocumentation for details.

Amp is designed to be modular, so if you think you have a great descriptor scheme or machine-learning model, you can try it out. This page describes how to add your own modules; starting with the bare-bones requirements to make it work, and building up with how to construct it so it integrates with respect to parallelization, etc.

10.1 Descriptor: minimal requirements

To build your own descriptor, it needs to have certain minimum requirements met, in order to play with *Amp*. The below code illustrates these minimum requirements:

```
from ase.calculators.calculator import Parameters

class MyDescriptor(object):

    def __init__(self, parameter1, parameter2):
        self.parameters = Parameters({'mode': 'atom-centered',})
        self.parameters.parameter1 = parameter1
        self.parameters.parameter2 = parameter2

    def tostring(self):
        return self.parameters.tostring()

    def calculate_fingerprints(self, images, cores, log):
        # Do the calculations...
        self.fingerprints = fingerprints # A dictionary.
```

The specific requirements, illustrated above, are:

- Has a parameters attribute (of type *ase.calculators.calculator.Parameters*), which holds the minimum information needed to re-build your module. That is, if your descriptor has user-settable parameters such as a cutoff radius, etc., they should be stored in this dictionary. Additionally, it must have the keyword “mode”; which must be set to either “atom-centered” or “image-centered”. (This keyword will be used by the model class.)

- Has a “tostring” method, which converts the minimum parameters into a dictionary that can be re-constructed using *eval*. If you used the *ASE Parameters* class above, this class is simple:

```
def tostring():
    return self.parameters.tostring()
```

- Has a “calculate_fingerprints” method. The images argument is a dictionary of training images, with keys that are unique hashes of each image in the set produced with `amp.utilities.hash_images()`. The log is a `amp.utilities.Logger` instance, that the method can optionally use as `log('Message')`. The cores key-word describes parallelization, and can safely be ignored if serial operation is desired. This method must save a sub-attribute `self.fingerprints` (which will be accessible in the main *Amp* instance as `calc.descriptor.fingerprints`) that contains a dictionary-like object of the fingerprints, indexed by the same keys that were in the images dictionary. Ideally, `descriptor.fingerprints` is an instance of `amp.utilities.Data`, but probably any mapping (dictionary-like) object will do.

A fingerprint is a vector. In **image-centered** mode, there is one fingerprint for each image. This will generally be just the Cartesian positions of all the atoms in the system, but transformations are possible. For example this could be accessed by the images key

```
>>> calc.descriptor.fingerprints[key]
>>> [3.223, 8.234, 0.0322, 8.33]
```

In **atom-centered** mode, there is a fingerprint for each atom in the image. Therefore, calling `calc.descriptor.fingerprints[key]` returns a list of fingerprints, in the same order as the atom ordering in the original ASE atoms object. So to access an individual atom’s fingerprints one could do

```
>>> calc.descriptor.fingerprints[key][index]
>>> ('Cu', [8.832, 9.22, 7.118, 0.312])
```

That is, the first item is the element of the atom, and the second is a 1-dimensional array which is that atom’s fingerprint.

Thus, `calc.descriptor.fingerprints[hash]` gives a list of fingerprints, in the same order the atoms appear in the image they were fingerprinted from.

If you want to train your model to forces also (besides energies), your “calculate_fingerprints” method needs to calculate derivatives of the fingerprints with respect to coordinates as well. This is because forces (as the minus of coordinate-gradient of the potential energy) can be written, according to the chain rule of calculus, as the derivative of your model output (which represents energy here) with respect to model inputs (which is fingerprints) times the derivative of fingerprints with respect to spatial coordinates. These derivatives are calculated for each image for each possible pair of atoms (within the cutoff distance in the **atom-centered** mode). They can be calculated either analytically or simply numerically with finite-difference method. If a piece of code is written to calculate coordinate-derivatives of fingerprints, then the “calculate_fingerprints” method can save it as a sub-attribute `self.fingerprintprimes` (which will be accessible in the main *Amp* instance as `calc.descriptor.fingerprintprimes`) along with `self.fingerprints`. `self.fingerprintprimes` is a dictionary-like object, indexed by the same keys that were in the images dictionary. Ideally, `descriptor.fingerprintprimes` is an instance of `amp.utilities.Data`, but probably any mapping (dictionary-like) object will do.

Calling `calc.descriptor.fingerprintprimes[key]` returns the derivatives of fingerprints for the image key of interest. This is a dictionary where each key is a tuple representing the indices of the derivative, and each value is a list of fingerprintprimes. (This list has the same length as the fingerprints.) For example, to retrieve derivatives of the fingerprints of atom indexed 2 (which is say Pt) with respect to *x* coordinate of atom indexed 1 (which is say Cu), we should do

```
>>> calc.descriptor.fingerprintprimes[key][(1, 'Cu', 2, 'Pt', 0)]
>>> [-1.202, 0.130, 4.511, -0.721]
```

Or to retrieve derivatives of the fingerprints of atom indexed 1 with respect to *z* coordinate of atom indexed 1, we do

```
>>> calc.descriptor.fingerprintprimes[key][(1, 'Cu', 1, 'Cu', 2)]
>>> [3.48, -1.343, -2.561, -8.412]
```

10.2 Descriptor: standard practices

The below describes standard practices we use in building modules. It is not necessary to use these, but it should make your life easier to follow standard practices. And, if your code is ultimately destined to be part of an Amp release, you should plan to make it follow these practices unless there is a compelling reason not to.

We have an example of a minimal descriptor in `amp.descriptor.example`; it's probably easiest to copy this file and modify it to become your new descriptor. For a complete example of a working descriptor, see `amp.descriptor.gaussian`.

10.2.1 The Data class

The key element we use to make our lives easier is the `Data` class. It should be noted that, in the development version, this is still a work in progress. The `Data` class acts like a dictionary in that items can be accessed by key, but also saves the data to disk (it is persistent), enables calculation of missing items, and can even parallelize these calculations across cores and nodes.

It is recommended to first construct a pure python version that fits with the `Data` scheme for 1 core, then expanding it to work with multiple cores via the following procedure. See the `Gaussian` descriptor for an example of implementation.

Basic data addition

To make the descriptor work with the `Data` class, the `Data` class needs a keyword *calculator*. The simplest example of this is our `NeighborlistCalculator`, which is basically a wrapper around ASE's `Neighborlist` class:

```
class NeighborlistCalculator:
    """For integration with .utilities.Data
    For each image fed to calculate, a list of neighbors with offset
    distances is returned.
    """

    def __init__(self, cutoff):
        self.globals = Parameters({'cutoff': cutoff})
        self.keyed = Parameters()
        self.parallel_command = 'calculate_neighborlists'

    def calculate(self, image, key):
        cutoff = self.globals.cutoff
        n = NeighborList(cutoffs=[cutoff / 2.] * len(image),
                        self_interaction=False,
                        bothways=True,
                        skin=0.)
        n.update(image)
        return [n.get_neighbors(index) for index in range(len(image))]
```

Notice there are two categories of parameters saved in the init statement: *globals* and *keyed*. The first are parameters that apply to every image; here the cutoff radius is the same regardless of the image. The second category contains data that is specific to each image, in a dictionary format keyed by the image hash. In this example, there are no keyed parameters, but in the case of the fingerprint calculator, the dictionary of neighborlists is an example of a *keyed*

parameter. The class must have a function called *calculate*, which when fed an image and its key, returns the desired value: in this case a neighborlist. Structuring your code as above is enough to make it play well with the *Data* container in serial mode. (Actually, you don't even need to worry about dividing the parameters into globals and keyed in serial mode.) Finally, there is a *parallel_command* attribute which can be any string which describes what this function does, which will be used later.

Parallelization

The parallelization should work provided the scheme is *embarrassingly parallel*; that is, each image's fingerprint is independent of all other images' fingerprints. We implement this in building the *Data* dictionaries, using a scheme of establishing SSH sessions (with *pxssh*) for each worker and passing messages with ZMQ.

The *Data* class itself serves as the master, and the workers are instances of the specific module; that is, for the Gaussian scheme the workers are started with *python -m amp.descriptor.gaussian id hostname:port* where *id* is a unique identifier number assigned to each worker, and *hostname:port* is the socket at which the workers should open the connection to the mater (e.g., "node243:51247"). The master expects the worker to print two messages to the screen: "<amp-connect>" which confirms the connection is established, and "<stderr>"; the text that is between them alerts the master (and the user's log file) where the worker will write its standard error to. All messages after this are passed via ZMQ. I.e., the bottom of the module should contain something like:

```
if __name__ == "__main__":
    import sys
    import tempfile

    hostsocket = sys.argv[-1]
    proc_id = sys.argv[-2]

    print('<amp-connect>')
    sys.stderr = tempfile.NamedTemporaryFile(mode='w', delete=False,
                                              suffix='.stderr')
    print('stderr written to %s<stderr>' % sys.stderr.name)
```

After this, the worker communicates with the master in request (from the worker) / reply (from the master) mode, via ZMQ. (It's worth checking out the [ZMQ Guide](#); (ZMQ Guide examples). Each request from the worker needs to take the form of a dictionary with three entries: "id", "subject", and (optionally) "data". These are easily created with the *MessageDictionary* class. The first thing the worker needs to do is establish the connection to the master and ask its purpose:

```
import zmq
from ..utilities import MessageDictionary
msg = MessageDictionary(proc_id)

# Establish client session via zmq; find purpose.
context = zmq.Context()
socket = context.socket(zmq.REQ)
socket.connect('tcp://%s' % hostsocket)
socket.send_pyobj(msg('<purpose>'))
purpose = socket.recv_pyobj()
```

In the final line above, the master has sent a string with the *parallel_command* attribute mentioned above. You can have some if/elif statements to choose what to do next, but for the *calculate_neighborlist* example, the worker routine is as simple as requesting the variables, performing the calculations, and sending back the results, which happens in these few lines. This is all that is needed for parallelization (in pure python):

```
# Request variables.
socket.send_pyobj(msg('<request>', 'cutoff'))
```

(continues on next page)

(continued from previous page)

```
cutoff = socket.recv_pyobj()
socket.send_pyobj(msg('<request>', 'images'))
images = socket.recv_pyobj()

# Perform the calculations.
calc = NeighborlistCalculator(cutoff=cutoff)
neighborlist = {}
while len(images) > 0:
    key, image = images.popitem() # Reduce memory.
    neighborlist[key] = calc.calculate(image, key)

# Send the results.
socket.send_pyobj(msg('<result>', neighborlist))
socket.recv_string() # Needed to complete REQ/REP.
```

Note that in python3, there is apparently an issue that garbage collection does not work correctly. Thus, we also need to call `socket.close()` on each `zmq.Context.socket` object before it is destroyed, otherwise the program may hang when trying to make new connections.

11.1 Fingerprint ranges

It is often useful to examine your fingerprints more closely. There is a utility that can help with that, an example of its use is below. This assumes you have open a calculator called “calc.amp” and you want to examine the fingerprint ranges for your training data.

```
from ase import io
from amp.descriptor.analysis import FingerprintPlot
from amp import Amp

calc = Amp.load('calc.amp')
images = io.read('training.traj', index=':')

fpplot = FingerprintPlot(calc)
fpplot(images)
```

This will create a plot that looks something like below, here showing the fingerprint ranges for the specified element.

You can also overlay a specific image’s fingerprint on to the fingerprint plot by using the *overlay* keyword when calling `fpplot`.

12.1 Visualizing neural network outputs

It can be useful to visualize the neural network model to see how it is behaving. For example, you may find nodes that are effectively shut off (e.g., always giving a constant value like 1) or that are acting as a binary switch (e.g., only returning 1 or -1). There is a tool to allow you to visualize the node outputs of a set of data.

```
from amp.model.neuralnetwork import NodePlot

nodeplot = NodePlot(calc)
nodeplot.plot(images, filename='nodeplottest.pdf')
```

This will create a plot that looks something like below. Note that one such series of plots is made for each element. Here, Layer 0 is the input layer, from the fingerprints. Layer 1 and Layer 2 are the hidden layers. Layer 3 is the output layer; that is, the contribution of Pt to the potential energy (before it is multiplied by and added to a parameter to bring it to the correct magnitude).

12.2 Calling an observer during training

It can be useful to call a function known as an “observer” during the training of the model. In the neural network implementation, this can be accomplished by attaching an observer directly to the model. The observer is executed at each call to `model.get_loss`, and is fed the arguments (self, vector, loss). An example of using the observer to print out one component of the parameter vector is shown below:

```
def observer(model, vector, loss):
    """Prints out the first component of the parameter vector."""
    print(vector[0])

calc.model.observer = observer
calc.train(images)
```

With this approach, all kinds of fancy tricks are possible, like calling *another* Amp model that reports the loss function on a test set of images. This could be useful to implement training with early stopping, for example.

13.1 Custom parameters

The Gaussian descriptor creates feature vectors based on the Behler scheme, and defaults to a small set of reasonable values. The values employed are always written to the log file and within saved instances of Amp calculators. You can specify custom parameters for the elements of the feature vectors as listed in the documentation of the `Gaussian` class.

There is also a helper function `make_symmetry_functions()` within the `amp.descriptor.gaussian` module to assist with this. An example of making a custom fingerprint is given below for a two-element system.

```
import numpy as np
from amp import Amp
from amp.descriptor.gaussian import Gaussian, make_symmetry_functions
from amp.model.neuralnetwork import NeuralNetwork

elements = ['Cu', 'Pt']
G = make_symmetry_functions(elements=elements, type='G2',
                           etas=np.logspace(np.log10(0.05), np.log10(5.),
                                             num=4),
                           offsets=[0., 2.])
G += make_symmetry_functions(elements=elements, type='G4',
                             etas=[0.005],
                             zetas=[1., 4.],
                             gammas=[+1., -1.])

G = {'Cu': G,
     'Pt': G}
calc = Amp(descriptor=Gaussian(Gs=G),
            model=NeuralNetwork())
```

To include angular symmetry functions of triplets inside the cutoff sphere but with distances larger than the cutoff radius you need to slightly modify the snippet above:

```
import numpy as np
from amp import Amp
from amp.descriptor.gaussian import Gaussian, make_symmetry_functions
from amp.model.neuralnetwork import NeuralNetwork

elements = ['Cu', 'Pt']
G = make_symmetry_functions(elements=elements, type='G2',
                           etas=np.logspace(np.log10(0.05), np.log10(5.),
                                             num=4),
                           offsets=[0., 2.])
G += make_symmetry_functions(elements=elements, type='G5',
                             etas=[0.005],
                             zetas=[1., 4.],
                             gammas=[+1., -1.])

G = {'Cu': G,
     'Pt': G}
calc = Amp(descriptor=Gaussian(Gs=G),
            model=NeuralNetwork())
```

CHAPTER 14

TensorFlow

Google has released an open-source version of its machine-learning software named Tensorflow, which can allow for efficient backpropagation of neural networks and utilization of GPUs for extra speed.

We have incorporated an experimental module that uses a tensorflow back-end, which may provide an acceleration particularly through access to GPU systems. As of this writing, the tensorflow code is in flux (with version 1.0 anticipated shortly).

14.1 Dependencies

This package requires google's TensorFlow 0.11.0. You can install it as shown below for Linux:

```
export TF_BINARY_URL=https://storage.googleapis.com/tensorflow/linux/cpu/tensorflow-0.
↪11.0-cp27-none-linux_x86_64.whl
pip install -U --upgrade $TF_BINARY_URL
```

or macOS:

```
export TF_BINARY_URL=https://storage.googleapis.com/tensorflow/mac/cpu/tensorflow-0.
↪11.0-py2-none-any.whl
pip install -U --upgrade $TF_BINARY_URL
```

If you want more information, please see [tensorflow's website](#) for instructions for installation on your system.

14.2 Example

```
#!/usr/bin/env python
"""Simple test of the Amp calculator, using Gaussian descriptors and neural
network model. Randomly generates data with the EMT potential in MD
simulations."""
```

(continues on next page)

(continued from previous page)

```

from ase.calculators.emt import EMT
from ase.build import fcc110
from ase import Atoms, Atom
from ase.md.velocitydistribution import MaxwellBoltzmannDistribution
from ase import units
from ase.md import VelocityVerlet
from ase.constraints import FixAtoms

from amp import Amp
from amp.descriptor.gaussian import Gaussian
from amp.model.tflow import NeuralNetwork

def generate_data(count):
    """Generates test or training data with a simple MD simulation."""
    atoms = fcc110('Pt', (2, 2, 2), vacuum=7.)
    adsorbate = Atoms([Atom('Cu', atoms[7].position + (0., 0., 2.5)),
                      Atom('Cu', atoms[7].position + (0., 0., 5.))])
    atoms.extend(adsorbate)
    atoms.set_constraint(FixAtoms(indices=[0, 2]))
    atoms.calc = EMT()
    MaxwellBoltzmannDistribution(atoms, 300. * units.kB)
    dyn = VelocityVerlet(atoms, dt=1. * units.fs)
    newatoms = atoms.copy()
    newatoms.calc = EMT()
    newatoms.get_potential_energy()
    images = [newatoms]
    for step in range(count - 1):
        dyn.run(50)
        newatoms = atoms.copy()
        newatoms.calc = EMT()
        newatoms.get_potential_energy()
        images.append(newatoms)
    return images

def train_test():
    label = 'train_test/calc'
    train_images = generate_data(2)
    convergence = {
        'energy_rmse': 0.02,
        'force_rmse': 0.02
    }

    calc = Amp(descriptor=Gaussian(),
               model=NeuralNetwork(hiddenlayers=(3, 3),
    ↪convergenceCriteria=convergence),
               label=label,
               cores=1)

    calc.train(images=train_images,)
    for image in train_images:
        print "energy =", calc.get_potential_energy(image)
        print "forces =", calc.get_forces(image)

if __name__ == '__main__':

```

14.3 Known issues

- *tflow* module does not work for versions different from 0.11.0.

14.4 About

This module was contributed by Zachary Ulissi (Department of Chemical Engineering, Stanford University, zulissi@gmail.com) with help, testing, and discussions from Andrew Doyle (Stanford) and the Amp development team.

CHAPTER 15

Bootstrap statistics

We have published a paper on systematically addressing uncertainty in atomistic machine learning, in which we focused on a basic bootstrap ensemble method:

Peterson, Christensen, and Khorshidi, “Addressing uncertainty in atomistic machine learning”, *PCCP* 19:10978-10985, 2017.

A helper module to create bootstrap calculators, which are capable of giving not just a mean model prediction, but uncertainty intervals, is described here. Note that you should use uncertainty intervals with caution, and, as we describe in the above paper, the “correct” interpretation of seeing large uncertainty bounds for a particular atomic configuration is that a new electronic structure calculation is required (at that configuration), and *not* that the true median will lie within those bounds.

15.1 Training

The below script shows a simple example of creating a bootstrap ensemble of 10 calculators for a small sample training set. (But you probably want an ensemble size much larger than 10 for reasonable statistics!)

```
from amp.utilities import Logger
from amp.stats.bootstrap import BootStrap

def generate_data(count, filename='training.traj'):
    """Generates test or training data with a simple MD simulation."""
    import os
    from ase import Atoms, Atom, units
    import ase.io
    from ase.calculators.emt import EMT
    from ase.build import fcc110
    from ase.md.velocitydistribution import MaxwellBoltzmannDistribution
    from ase.md import VelocityVerlet
    from ase.constraints import FixAtoms
    if os.path.exists(filename):
```

(continues on next page)

(continued from previous page)

```

    return
    traj = ase.io.Trajectory(filename, 'w')
    atoms = fcc110('Pt', (2, 2, 2), vacuum=7.)
    atoms.extend(Atoms([Atom('Cu', atoms[7].position + (0., 0., 2.5)),
                        Atom('Cu', atoms[7].position + (0., 0., 5.))]))
    atoms.set_constraint(FixAtoms(indices=[0, 2]))
    atoms.calc = EMT()
    atoms.get_potential_energy()
    traj.write(atoms)
    MaxwellBoltzmannDistribution(atoms, 300. * units.kB)
    dyn = VelocityVerlet(atoms, dt=1. * units.fs)
    for step in range(count - 1):
        dyn.run(50)
        traj.write(atoms)

generate_data(5, 'training.traj')

calc_text = """
from amp import Amp
from amp.descriptor.gaussian import Gaussian
from amp.model.neuralnetwork import NeuralNetwork
from amp.model import LossFunction

calc = Amp(descriptor=Gaussian(),
            model=NeuralNetwork(),
            dblabel='./amp-db',
            envcommand='loadamp')
calc.model.lossfunction = LossFunction(force_coefficient=0.,
                                       convergence={'force_rmse': None})
"""

start_command = 'python run.py'

calc = Bootstrap(log=Logger('bootstrap.log'))
calc.train(images='training.traj', n=10, calc_text=calc_text,
          start_command=start_command, label='bootstrap')

```

Run the above script once and wait for it to finish (probably <1 minute). You will see lots of directories created with the ensemble calculators. Run the same script *again*, and it will clean up / archive these directories into a compressed (.tar.gz) file, and create a calculator parameters file called 'bootstrap.ensemble', which you can load with *Bootstrap(load='bootstrap.ensemble')*, as described later.

First, some notes on the above. The individual calculators are created with the *calc_text* variable in the above script; you can modify things like neural network size or convergence criteria in this text block.

In the above, the optional *start_command* is the command to start the job, which defaults to "python run.py". Here, it runs each calculator's training sequentially; that is, after one finishes it starts the next. If your machine has >10 cores, or you don't mind the training processes all competing for resources, you can have them all run in parallel by placing an ampersand (in *nix systems) at the end of this line, that is "python run.py &".

Most likely, you want to run this on a high-performance computing cluster that uses a queuing system. In this case, *start_command* is your queuing command, for our SLURM system this is just

```
start_command = 'sbatch run.py'
```

If you need to supply headerlines to your queuing system, you can do them with something like the below.

```
headerlines = """#SBATCH --time=00:30:00
#SBATCH --nodes=1
#SBATCH --ntasks-per-node=8
#SBATCH --partition=batch
"""

...

calc.train(images='training.traj', n=10, train_line=train_line,
           calc_text=calc_text, headerlines=headerlines,
           start_command=start_command, label='bootstrap')
```

In a similar way, you can also supply a custom *train_line* if necessary; see the module's autodocumentation for details.

15.2 Loading and using

The bootstrap ensemble can be loaded via the calculator's load keyword. The below script shows an example of loading the calculator, and using it to predict the energies and the spread of the ensemble for the training images.

```
import ase.io
from amp.stats.bootstrap import BootStrap

calc = BootStrap(load='bootstrap.ensemble')

traj = ase.io.Trajectory('training.traj')

for image in traj:
    energies = calc.get_potential_energy(image,
                                         output=(0.05, 0.5, 0.95))
    print(energies)
    energy = image.get_potential_energy()
    print(energy)
```

Note that the call to *calc.get_potential_energy* returns *three* energy predictions, at the 5th, 50th (median), and 95th percentile, as specified with the tuple (0.05, 0.5, 0.95). When you run this, you should see that the median prediction matches the true energy (from *image.get_potential_energy*) quite well, while the spread in the data is due to the sparsity of data; as described in our paper above, this ensemble technique punishes regions of the potential energy surface with infrequent data.

15.3 Hands-free training

In typical use, calling the *train()* method of the *BootStrap* class will spawn many independent training jobs. Subsequent calls to *train* will help you manage those jobs: checking which have converged, checking which failed to converge (and re-submitting them), checking which timed out (and re-submitting them), and, if all converged, creating a bundled calculator. It can be most efficient to submit a (single-core) job that repeatedly calls this command for you and acts as a job manager until all the training jobs are complete. This can be achieved by taking advantage of the *results* dictionary returned by *train*, as in the below example script which uses SLURM environment commands.

```
#!/usr/bin/env python
#SBATCH --time=50:00:00
#SBATCH --nodes=1
```

(continues on next page)

(continued from previous page)

```
#SBATCH --ntasks-per-node=1
#SBATCH --partition=batch

import time
from amp.stats.bootstrap import BootStrap
from amp.utilities import Logger

calc_text = """
from amp import Amp
from amp.model.neuralnetwork import NeuralNetwork
from amp.descriptor.gaussian import Gaussian
from amp.model import LossFunction

calc = Amp(model=NeuralNetwork(),
            descriptor=Gaussian(),
            dblabel='../amp-db')
calc.model.lossfunction = LossFunction(convergence={'force_rmse': 0.02,
                                                    'force_maxresid': 0.03})
"""

headerlines = """#SBATCH --time=05:30:00
#SBATCH --nodes=1
#SBATCH --ntasks-per-node=8
#SBATCH --partition=batch
"""

start_command = 'sbatch run.py'

calc = BootStrap(log=Logger('bootstrap.log'))

complete = False
count = 0
while not complete:
    results = calc.train(images='training.traj',
                          n=50,
                          calc_text=calc_text,
                          start_command=start_command,
                          label='bootstrap',
                          headerlines=headerlines,
                          expired=360.)
    calc.log('train loop: ' + str(count))
    count += 1
    complete = results['complete']
    time.sleep(120.)
```

Nearsighted force training

We have published a paper on the nearsighted force-training (NFT) approach, in which we used an ensemble-based atomic uncertainty metric to systematically generate small structures to address uncertain local chemical environments:

Zeng, Chen and Peterson, “A nearsighted force-training approach to systematically generate training data for the machine learning of large atomic structures “. *JCP* 156, 064104 (2022).

We introduce a module to train an ensemble of bootstrap calculators in an active learning scheme, which aims to address uncertain local chemical environments in a large structure iteratively. We first train bootstrap calculators on an initial training set comprising of simple bulk structures. Next, we quantify atomic uncertainties on a large target structure, as the standard deviation of force predictions of the bootstrap calculators multiplied by a constant coefficient. We extract atomic “chunks” centered on the most uncertain atoms, and evaluated those “chunks” by single point calculations. We then extend the training set by the calculated “chunks”, and we retrain the bootstrap calculators until a certain stopping criterion is satisfied. For the retraining with atomic “chunks”, it is crucial that only the forces on central atoms are trained, which is the reason why this approach is termed as “nearsighted force training”.

16.1 Automatic protocol

The example script at below shows how to train bootstrap calculators based on the nearsighted force-training automatic protocol.

```
from amp.nft.activelearner import NFT
from amp.utilities import Logger

calc_text = """
from amp import Amp
from amp.model import LossFunction
from amp.descriptor.gaussian import Gaussian
from amp.model.neuralnetwork import NeuralNetwork

hl = [5, 5]
calc = Amp(model=NeuralNetwork(hiddenlayers=hl),
            descriptor=Gaussian(),
```

(continues on next page)

(continued from previous page)

```

        dblabel='../amp-data')
calc.model.lossfunction = LossFunction(convergence={'energy_rmse': 0.001,
                                                    'force_rmse':0.005,
                                                    'force_maxresid': 0.02})

"""
al = NFT(stop_delta=0.02, max_iterations=20, steps_not_improved=2,
        threshold=-0.9)

traj = 'initial_images.traj'
target_image = 'pt260.traj'
start_command = 'python run.py'

al.run(images=traj, target_image=target_image, n=10,
       calc_text=calc_text, start_command=start_command,
       parent_calc=EMT(), cutoff=6.5)

```

Once the active learning is stopped, the bootstrap calculators giving the best results will be saved as *best.[label].ensemble*. The intermediate results will be saved inside the training folder in a folder named “saved-info”, which includes the trajectory and indices of selected atomic chunks, and atomic uncertainties of the target structure at each NFT iteration. Indices and atomic uncertainties are saved in the **ndarray** format.

The active learning will be terminated if either condition at below is met—those conditions are supplied as parameters for the `:py:class:`~amp.nft.activelearner.NFT`` class.

- *stop_delta* controls the convergence structure uncertainty (maximum atomic uncertainty in the target structure).
- *max_iterations* controls the maximum allowed number of NFT iterations.
- *steps_not_improved* defines the number of consecutive NFT iterations to stop the NFT procedure if the structure uncertainty has not been improved.

The *threshold* controls the number of atomic “chunks” extracted from the target structure to be evaluated in single-point calculations. For example, *threshold=-0.9* indicates that “chunks” with the top 10% atomic uncertainties will be calculated in electronic structures.

Calling `run()` method will spawn many independent training jobs, here $n=10$ jobs. Details of each job is given in the *calc_text*, and the jobs are submitted with the *start_command*. For details about those two parameters, we refer the readers to the documentation regarding the [Bootstrap statistics](#). The initial bootstrap calculators are trained on *initial_images.traj*, and the uncertainty evaluation is targeted on *pt260.traj*. The *parent_calc* is the electronic structure method to perform single-point calculations on atomic “chunks”. The *cutoff* controls the range of atoms to be included in an atomic “chunk”.

Fingerprint databases

Often, a user will want to train multiple calculators to a common set of images. This may be just in routine development of a trained calculator (e.g., trying different neural network sizes), in using multiple training instances trying to find a good initial guess of parameters, or in making a committee of calculators. In this case, it can be a waste of computational time to calculate the fingerprints (and more expensively, the fingerprint derivatives) more than once.

To deal with this, Amp saves the fingerprints to a database, the location of which can be specified by the user. If you want multiple calculators to avoid re-fingerprinting the same images, just point them to the same database location.

17.1 Format

The database format is custom for Amp, and is designed to be as simple as possible. Amp databases end in the extension *.ampdb*. In its simplest form, it is just a directory with one file per image; that is, you will see something like below:

```
label-fingerprints.ampdb/  
  loose/  
    f60b3324f6001d810afbab9f85a6ea5f  
    aeaaaa21e5facc62bae94c5c48b04031
```

In the above, each file in the directory “loose” is the hash of an image, and contains that image’s fingerprint. We use a file-based “database” to avoid conflicts with multiple processes accessing a database at the same time, which can cause conflicts.

However, for large training sets this can lead to lots of loose files, which can eat up a lot of memory, and with the large number of files slow down indexing jobs (like backups and scans). Therefore, you can compress the database with the *amp-compress* tool, described below.

17.2 Compress

To save disk space, you may periodically want to run the utility *amp-compress* (contained in the *tools* directory of the amp package; this should be on your path for normal installations). In this case, you would run *amp-compress*

`<filename>`, which would result in the above `.ampdb` file being changed to:

```
label-fingerprints.ampdb/  
  archive.tar.gz  
  loose/
```

That is, the two fingerprints that were in the “loose” directory are now in the file “archive.tar.gz”.

You can also use the `-recursive` (or `-r`) flag to compress all `ampdb` files in or below the specified directory.

When Amp reads from the above database, it first looks in the “loose” directory for the fingerprint. If it is not there, it looks in “archive.tar.gz”. If it is not there, it calculates the fingerprint and adds it to the “loose” directory.

17.3 Future

We plan to make the `amp-compress` tool more automated. If the user does not supply a separate `dblabel` keyword, then we assume that their process is the only process using the database, and it is safe to compress the database at the end of their training job. This would automatically clean up the loose files at the end of the job.

CHAPTER 18

Fast Force Calls

Force calls (or potential-energy calls) are done inside Amp in a single thread, which means they should be fast compared to something like DFT, but inherently much slower than an optimized molecular dynamics code. If you would like to run big, fast simulations, it's advisable to link the output of Amp to such a code, then run your simulation in a molecular dynamics code.

Here, we describe three ways to do fast force calls in Amp using n2p2, PROPhet/LAMMPS and KIM/LAMMPS interface, respectively. As of this writing, the former two approaches are more stable.

18.1 Using n2p2

n2p2 is a ready-to-use software for high-dimensional neural network potentials, originally developed by Andreas Singraber at the University of Vienna. Importantly, it provides python interface for fast predictions of energy and forces, which makes it really easy to be incorporated into other python-based code, such as Amp. It also allows using existing neural network potentials in LAMMPS. The LAMMPS NNP interface is detailed in the [documentation](#).

The connection from Amp to n2p2's fast force calls is made possible via a utility function `amp.convert.save_to_n2p2()` written by Cheng Zeng (Brown). If you use this interface with Amp, please cite the n2p2 paper in addition to the Amp paper:

Singraber, A.; Behler, J.; Dellago, C. Library-Based LAMMPS Implementation of High-Dimensional Neural Network Potentials. *J. Chem. Theory Comput.* 2019, 15 (3), 1827–1840.

In the next, an example for using this interface is described. Suppose you have a trained Amp calculator saved as “amp.amp”, and you want to predict on an image in a trajectory file ‘image.traj’, you can convert the Amp calculator and the ASE trajectory to n2p2 input files by :

```
from amp import Amp
from amp.convert import save_to_n2p2
from ase.io import read

calc = Amp.load('amp.amp')
desc_pars = calc.descriptor.parameters
```

(continues on next page)

(continued from previous page)

```
model_pars = calc.model.parameters
atoms = read('image.traj')
save_to_n2p2(desc_pars, model_pars, images=atoms)
```

Then you can make prediction via the python interface shown below:

```
import pynnp

# Initialize NNP prediction mode.
p = pynnp.Prediction()
# Read settings and setup NNP.
p.setup()
# Read in structure.
p.readStructureFromFile()
# Predict energies and forces.
p.predict()
# Shortcut for structure container.
s = p.structure
print("-----")
print("Structure 1:")
print("-----")
print("numAtoms           : ", s.numAtoms)
print("numAtomsPerElement : ", s.numAtomsPerElement)
print("-----")
print("Energy (Ref) : ", s.energyRef)
print("Energy (NNP) : ", s.energy)
print("-----")
forces = []
for atom in s.atoms:
    print(atom.index, atom.f.r)
```

or simply use a command:

```
$ nnp-predict 1
```

18.2 Using PROPhet/LAMMPS

PROPhet was a nice atomistic machine-learning code developed by Brian Kolb and Levi Lentz in the group of Alexie Kolpak at MIT.

[illegible]

Included in PROPhet was a potential that could be installed into LAMMPS (a very fast molecular dynamics code); this potential allowed for neural-network potentials in the Behler–Parinello scheme to run in LAMMPS. If you install this potential into your own copy of LAMMPS, you can then use the utility function `amp.convert.save_to_prophet()` to output your data in a format where you can use LAMMPS for your force calls.

The work of making the connection from Amp to PROPhet’s LAMMPS potential was done by Efrem Braun (Berkeley), Levi Lentz (MIT), and August Edwards Guldberg Mikkelsen (DTU). If you use this interface with Amp, please cite the PROPhet paper in addition to the Amp paper in any publications that result:

Kolb, Lentz & Kolpak, “Discovering charge density functionals and structure-property relationships with PROPhet: A general framework for coupling machine learning and first-principles methods”, *Scientific Reports* 7:1192, 2017.

The instructions below assume you are on a linux-like system and have Amp already installed. It also uses git to download codes and change branches. Create a folder, where everything will be stored called (e.g., LAMPHET) and go into it:

```
$ mkdir LAMPHET
$ cd LAMPHET
```

Download the latest stable LAMMPS version into the LAMPHET directory:

```
$ git clone https://github.com/lammps/lammps.git
```

For this purpose, we will not be using the PROPhet version from the official repository, but instead from this [fork](#). Download it and then change to the amp compatible branch:

```
$ git clone https://github.com/Augustegm/PROPhet.git
$ cd PROPhet
$ git checkout amp_compatible
```

Now we need to set the following environment variables in our `.bashrc`:

```
export LAMPHET=path_to_your_codes/LAMPHET
export PROPhet_DIR=$LAMPHET/PROPhet/src
export LAMMPS_DIR=$LAMPHET/lammps/src
export PATH=$PATH:$LAMMPS_DIR
export PYTHONPATH=$LAMPHET/lammps/python:$PYTHONPATH
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$LAMPHET/lammps/src
```

The next step is to compile PROPhet. To do this correctly, you will need to first write the *Makefile* and then we will manually edit it:

```
$ cd $PROPhet_DIR
$ ./configure --prefix=$LAMPHET/prophet-install --enable-lammps=$LAMMPS_DIR
```

Append `-fPIC` to line 8 in the *Makefile*. It should look like one of the two lines below:

```
CFLAGS = -O3 -DUSE_MPI -fPIC
CFLAGS = -O3 -fPIC
```

Now build PROPhet by typing:

```
$ make
```

The next step is to compile LAMMPS. To do this we first need to copy over a file from PROPhet:

```
$ cd $LAMMPS_DIR
$ cp $PROPhet_DIR/pair_nn.h .
```

We also need to change some lines in the *Makefile.package.empty* file. Edit lines 4-6 to:

```
PKG_INC = -I$(PROPhet_DIR)
PKG_PATH = -L$(PROPhet_DIR)
PKG_LIB = -lPROPhet_lammps
```

Now we can compile LAMMPS. It is recommended to compile it in the four different ways giving a serial and parallel version as well as shared library versions, which are needed if one wants to use it from Python (needed for using the LAMMPS interface in ASE):

```
$ make serial
$ make mpi
$ make serial mode=shlib
$ make mpi mode=shlib
```

18.3 Using OpenKIM

Note: The forces predicted with the KIM approach may not be compatible with Amp forces as described in these [merge-request comments](#). Use this approach with caution.

Machine-learning parameters trained in *Amp* can be used to perform fast molecular dynamics simulations, via the [Knowledge Base for Interatomic Models](#) (KIM). LAMMPS recognizes *kim* as a pair style that interfaces with the KIM repository of interatomic potentials.

To build LAMMPS with the KIM package you must first install the KIM API (library) on your system. Below are the minimal steps you need in order to install the KIM API. After KIM API is installed, you will need to install LAMMPS from its [github repository](#). Finally we will need to install the model driver that is provided in the *Amp* repository. In the followings we discuss each of these steps.

In this installation instruction, we assume that the following requirements are installed on your system:

- git
- make
- cmake (If it is not installed on your system see [here](#).)
- GNU compilers (gcc, g++, gfortran) version 4.8.x or higher.

18.3.1 Installation of KIM API

You can follow the instructions given at the OpenKIM [github repository](#) to install KIM API. In short, you need to clone the repository by:

```
$ git clone https://github.com/openkim/kim-api.git
```

Next do the following:

```
$ cd kim-api-master && mkdir build && cd build
$ FC=gfortran-4.8 cmake .. -DCMAKE_BUILD_TYPE=Release
$ make
$ sudo make install
$ sudo ldconfig
```

The second line forces cmake to use gfortran-4.8 as the fortran compiler. We saw gfortran-5 throws error “Error: TS 29113/TS 18508: Noninteroperable array” but gfortran-4.8 should work fine. Now you can list model and model drivers available in KIM API by:

```
$ kim-api-collections-management list
```

or install and remove models and model drivers, etc. For a detailed explanation of possible options see [here](#).

18.3.2 Building LAMMPS

Clone LAMMPS source files from the [github repository](https://github.com/lammps/lammps):

```
$ git clone https://github.com/lammps/lammps.git
```

Now you can do the following to build LAMMPS:

```
$ cd lammps && mkdir build && cd build
$ cmake -D CMAKE_C_COMPILER=gcc -D CMAKE_CXX_COMPILER=g++ -D CMAKE_Fortran_
  ↳COMPILER=gfortran -D PKG_KIM=on -D KIM_LIBRARY="/usr/local/lib/libkim-api.so" -D_
  ↳KIM_INCLUDE_DIR="/usr/local/include/kim-api" ../cmake
$ make
```

18.3.3 Installation of *amp_model_driver*

Now you are ready to install the *amp_model_driver* provided on this repository. To do that first change to *amp-kim* directory by:

```
$ cd /amp_directory/amp/tools/amp-kim/
```

where *amp_directory* is where your *Amp* source files are located.

Then make a copy of the fortran modules inside the *amp_model_driver* directory by:

```
$ cp ../../amp/descriptor/gaussian.f90 amp_model_driver/gaussian.F90
$ cp ../../amp/descriptor/cutoffs.f90 amp_model_driver/cutoffs.F90
$ cp ../../amp/model/neuralnetwork.f90 amp_model_driver/neuralnetwork.F90
```

Finally you can install the *amp_model_driver* by:

```
$ kim-api-collections-management install user ./amp_model_driver
```

You can now remove the fortran modules that you copied earlier:

```
$ rm amp_model_driver/gaussian.F90
$ rm amp_model_driver/cutoffs.F90
$ rm amp_model_driver/neuralnetwork.F90
```

18.3.4 Installation of *amp_parametrized_model*

Now that you have *amp_model_driver* installed, you need to install the parameters also as the final step. **Note that this is the only step that you need to repeat when you change the parameters of the machine-learning model.** You should first parse all of the parameters of your *Amp* calculator to a text file by:

```
from amp import Amp
from amp.convert import save_to_openkim

calc = Amp(...)
calc.train(...)
save_to_openkim(calc)
```

where the last line parses the parameters of the *calc* object into a text file called *amp.params*.

You should then copy the generated text file into the *amp_parameterized_model* sub-directory of the *Amp* source directory:

```
$ cp /working_directory/amp.params amp_directory/amp/tools/amp-kim/amp_parameterized_  
↪model/.
```

where *working_directory* is where *amp.params* is located initially, and *amp_directory* is the directory of the *Amp* source files. Finally you change back to the *amp-kim* directory by:

```
$ cd /amp_directory/amp/tools/amp-kim/
```

Note that installation of *amp_parameterized_model* will not work without *amp.params* being located in the */amp_directory/amp/tools/amp-kim/amp_parameterized_model* directory. Next install your parameters by:

```
$ kim-api-collections-management install user ./amp_parameterized_model
```

Congrats! Now you are ready to use the *Amp* calculator with *amp.params* in you molecular dynamics simulation by an input file like this:

```
variable      x index 1  
variable      y index 1  
variable      z index 1  
  
variable      xx equal 10*$x  
variable      yy equal 10*$y  
variable      zz equal 10*$z  
  
units         metal  
atom_style    atomic  
  
lattice       fcc 3.5  
region        box block 0 ${xx} 0 ${yy} 0 ${zz}  
create_box    1 box  
create_atoms  1 box  
mass          1 1.0  
  
velocity      all create 1.44 87287 loop geom  
  
pair_style     kim amp_parameterized_model  
pair_coeff     * * Pd  
  
neighbor       0.3 bin  
neigh_modify   delay 0 every 20 check no  
  
fix           1 all nve  
  
run           10
```

which, for example, is an input script for LAMMPS to do a molecular dynamics simulation of a Pd system for 10 units of time.

This page contains standard practices for developing Amp, focusing on repositories and documentation.

19.1 Official repository

The official Amp repository lives on bitbucket, [andrewpeterson/amp](https://bitbucket.org/andrewpeterson/amp). We employ a branching model where the *master* branch is the main development branch, containing day-to-day commits from the core developers and honoring merge requests from others. From time to time, we create a new branch that corresponds to a release. This release branch contains only the tagged release and any bug fixes.

19.2 Contributing

You are welcome to contribute new features, bug fixes, better documentation, etc., to Amp. If you would like to contribute, please create a private fork and a branch for your new commits. When it is ready, send us a merge request. We follow the same basic model as ASE. Please see the ASE documentation for complete instructions; a summary is also listed below.

As good coding practice, make sure your code passes both the pyflakes and pep8 tests. (On linux, you should be able to run `pyflakes file.py` and `pep8 file.py`; then correct your code until the warnings disappear.) If adding a new feature: please add a (very brief) test to the tests folder to ensure your new code continues to work as the project evolves, and also be sure to write clear documentation. Finally, to make users aware of your new feature or change, add a bullet point to the release notes page of the documentation under the Development version heading.

It is also a good idea to send us an email if you are planning something complicated.

19.3 Your fork and branches

If you would like to contribute, here is our recommended way of using git to ultimately create a merge request that contains all of your changes to be included in *Amp*.

Initial setup. First, create an account on bitbucket, and from the official Amp repository click the button to create a *fork* into your own account. From the website for your fork, find the button to clone it, and use this to create a copy on your own filesystem. This means you will run a command similar to this on your own machine:

```
git clone git@bitbucket.org:myusername/amp.git
```

On your local computer, the term “origin” will refer to your own fork of Amp; we will also need to be able to access the original fork; we’ll name this “upstream” and link it with a command like:

```
git remote add upstream git@bitbucket.org:andrewpeterson/amp.git
```

You can check that the above makes sense by running *git remote -v*.

Making changes. Before making any changes, it’s a good idea to make sure your local copy is up-to-date with the parent fork. You can do this with

```
git checkout master # Make sure we are on the right branch.
git pull upstream master
```

To make changes, first create a local branch with a descriptive name, for example “fix-fingerprints”. You can do this with

```
git checkout -b fix-fingerprints
```

Your local code is now in a new branch, which you can verify by typing *git status* (or *git branch* to see all your branches). Now, go ahead and edit your code and commit your changes with *git commit*. You can make as many commits to your local copy as you like as you develop. When you think your code is ready to be part of the official Amp repository, first make sure it is still up-to-date with the upstream repository, then push your branch to your own fork:

```
git pull upstream master
git push origin fix-fingerprints
```

Now you are ready to put in a merge request. You will likely see a local message telling you how to do this after you push, but if not, just go to your own bitbucket page, open the branch there, and look for a button for a merge request. Type a clear description and submit.

If you’d like to discuss some aspects of your code before it is ready, you can do the above but prefix the merge request title with “WIP: ” (work in progress). Then others can review your code before you submit it officially.

19.4 Documentation

This documentation is built with sphinx. (Mkdocs doesn’t seem to support autodocumentation.) To build a local copy, cd into the docs directory and try a command such as

```
sphinx-build . /tmp/ampdocs
firefox /tmp/ampdocs/index.html & # View the local copy.
```

This uses the style “bizstyle”; if you find this is missing on your system, you can likely install it with

```
pip install --user sphinxjp.themes.bizstyle
```

You should then be able to update the documentation rst files and see changes on your own machine. For line breaks, please use the style of containing each sentence on a new line.

19.5 Releases

To create a release, we go through the following steps.

- Reserve a DOI for the new release via zenodo.org. Do this by creating a new upload, and choosing “pre-reserve” before adding any files.
- Prepare the master branch for the release. (1) Update Release Notes, where the changes should have been catalogued under a “Development version” heading; move these to a new heading for this release, along with a release date and the DOI from above. (2) Also note the latest stable release on the index.rst page.
- Create a new branch on the bitbucket repository with the version name, as in *v0.5*. (Don’t create a separate branch if this is a bugfix release, e.g., 0.5.1 — just add those to the v0.5 branch.) Note the branch name starts with “v”, while the tag names will not, to avoid naming conflicts.
- Check out the new branch to your local machine (e.g., *git fetch && git checkout v0.5*). All subsequent work is in the new branch.
- Change *amp/VERSION* to reflect the release number (without ‘beta’). Note this will automatically change it in docs/conf.py, the Amp log files, and setup.py.
- On the Release Notes page, delete the “Development version” heading.
- Commit and push the changes to the new branch on bitbucket.
- Tag the release with the release number, e.g., ‘0.5’ or ‘0.5.1’, the latter being for bug fixes. Do this on a local machine (on the correct branch) with *git tag -a 0.5*, followed by *git push origin -tags*.
- Add the version to readthedocs’ available versions; also set it as the default stable version. (This may already be done automatically.)
- Upload an archive and finalize the DOI via zenodo.org. Note that all the “.git” files and folders should be removed from the .tar.gz archive before uploading to Zenodo.
- Prepare and upload to PyPI (for pip):

```
$ python3 setup.py sdist
$ twine upload dist/*
```

- Send a note to the amp-users list summarizing the release.
- In the master branch, update the VERSION file to reflect the new beta version.

Module autodocumentation:

CHAPTER 20

Main

This module is the main part of the Amp package.

20.1 Module contents

CHAPTER 21

Descriptor

The descriptor module contains methods for describing the local atomic environment; that is, feature vectors that can be fed to machine-learning modules.

21.1 Gaussian

21.2 Zernike

21.3 Bispectrum

21.4 Cutoff functions

21.5 Example

(This contains just a minimal example of how to build your own descriptor.)

This module is designed to include machine-learning models for interpolating energies and forces from either an atom-centered or image-centered fingerprint description.

22.1 Model

22.2 Neural Network

22.3 Tensorflow Neural Network

A work in progress, this module *amp.model.tflow* uses Google's TensorFlow package to implement a neural network, which may provide GPU acceleration and other advantages.

CHAPTER 23

Regression

This module includes a regressor object used to optimize the parameters of the machine-learning model.

23.1 Module contents

CHAPTER 24

Utilities

This module contains utilities for use with various aspects of the Amp calculator.

24.1 Module contents

CHAPTER 25

Analysis

Tools for analysis of output exist here.

25.1 Module contents

The stats module contains a bootstrap method for addressing uncertainty.

26.1 Bootstrap

CHAPTER 27

Convert

Tools for interconverting data between codes.

27.1 Module contents

The preprocess module contains methods for image and feature selections.

28.1 Image selection

28.2 Feature selection

The nft module contains methods for generating initial images, and the active learning protocol based on the near-sighted force-training approach.

29.1 Initialization

29.2 NFT active learning

Indices and tables

- `genindex`
- `modindex`
- `search`
